# **Chapter 3: Processes**

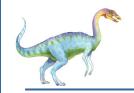

#### **Chapter 3: Processes**

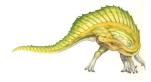

- Process Concept
- Process Scheduling
- Operations on Processes
- Interprocess Communication
- □ IPC in Shared-Memory Systems
- □ IPC in Message-Passing Systems

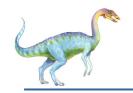

# **Objectives**

- Identify the separate components of a process and illustrate how they are represented and scheduled in an operating system.
- Describe how processes are created and terminated in an operating system.
- Describe and contrast interprocess communication using shared memory and message passing.

# **Process Concept**

- Program is passive entity stored on disk (executable file); process is active
  - Program becomes process when executable file loaded into memory
- Execution of program started via GUI mouse clicks, command line entry of its name, etc
- One program can be several processes
  - Consider multiple users executing the same program

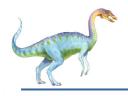

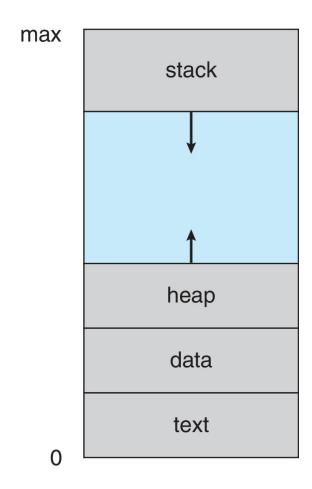

# **Process Concept (Cont.)**

- An operating system executes a variety of programs that run as a process.
- Process a program in execution; process execution must progress in sequential fashion
- Multiple parts
  - The program code, also called text section
  - Current activity including program counter, processor registers
  - Stack containing temporary data
    - Function parameters, return addresses, local variables
  - Data section containing global variables
  - Heap containing memory dynamically allocated during run time

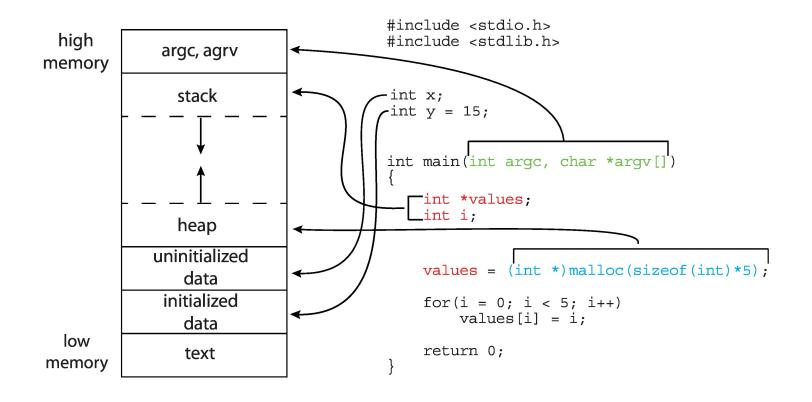

# **Process in Memory**

# **Memory Layout of a C Program**

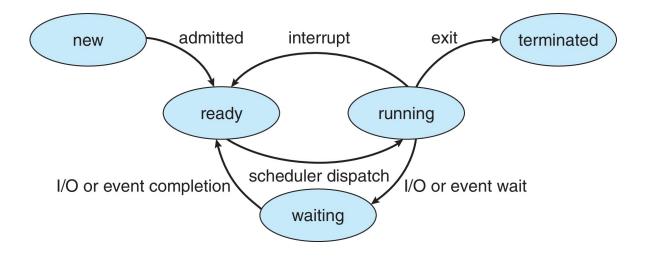

#### **Process State**

- As a process executes, it changes state
  - New: The process is being created
  - Running: Instructions are being executed
  - Waiting: The process is waiting for some event to occur
  - □ **Ready**: The process is waiting to be assigned to a processor
  - Terminated: The process has finished execution

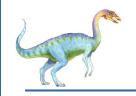

# **Diagram of Process State**

# **Process Control Block (PCB)**

Information associated with each process (also called task control block)

- □ Process state running, waiting, etc
- Program counter location of instruction to next execute
- CPU registers contents of all processcentric registers
- CPU scheduling information- priorities, scheduling queue pointers
- Memory-management information memory allocated to the process
- Accounting information CPU used, clock time elapsed since start, time limits
- □ I/O status information I/O devices allocated to process, list of open files

process state
process number
program counter
registers
memory limits
list of open files

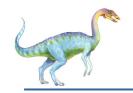

#### **Threads**

- □ So far, process has a single thread of execution
- Consider having multiple program counters per process
  - Multiple locations can execute at once
    - Multiple threads of control -> threads
- Must then have storage for thread details, multiple program counters in PCB

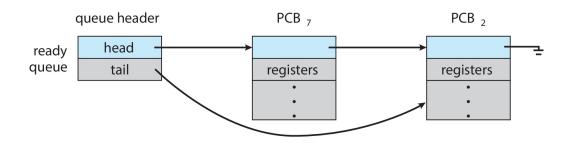

# **Process Scheduling**

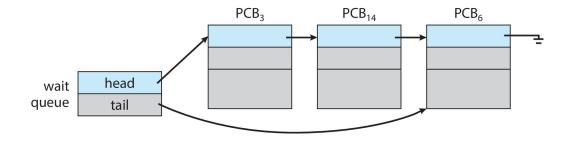

- Maximize CPU use, quickly switch processes onto CPU core
- Process scheduler selects among available processes for next execution on CPU core
- Maintains scheduling queues of processes
  - Ready queue set of all processes residing in main memory, ready and waiting to execute
  - Wait queues set of processes waiting for an event (i.e. I/O)
  - Processes migrate among the various queues

#### **Ready and Wait Queues**

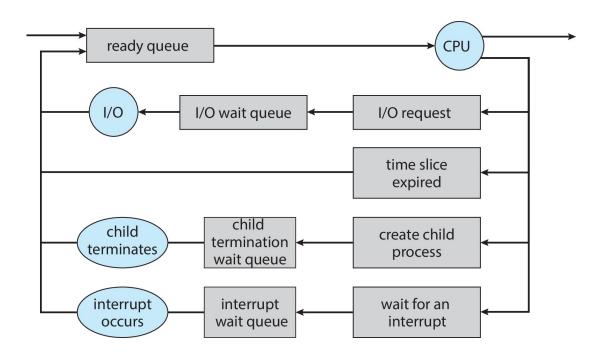

#### Representation of Process Scheduling

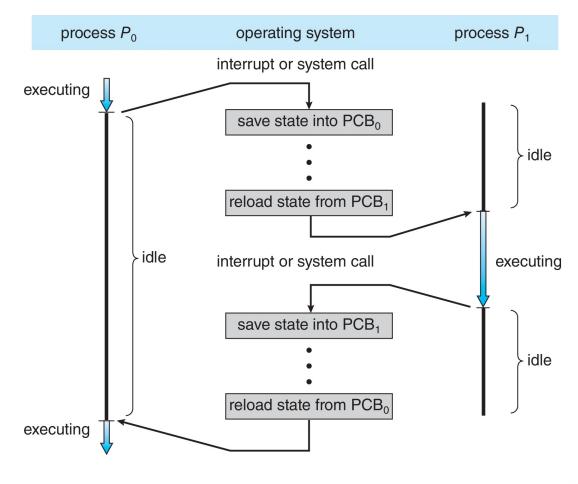

# **CPU Switch From Process to Process**

A **context switch** occurs when the CPU switches from one process to another.

#### **Context Switch**

- When CPU switches to another process, the system must save the state of the old process and load the saved state for the new process via a context switch
- Context of a process represented in the PCB
- Context-switch time is overhead; the system does no useful work while switching
  - □ The more complex the OS and the PCB → the longer the context switch
- Time depends on hardware support
  - Some hardware provides multiple sets of registers per CPU
    - → multiple contexts loaded at once

# Multitasking in Mobile Systems

- Some mobile systems (e.g., early version of iOS) allow only one process to run, others suspended
  - Single foreground process- controlled via user interface
  - Multiple background processes— in memory, running, but not on the display, and with limits
  - Limits include single, short task, receiving notification of events, specific long-running tasks like audio playback
- Android runs foreground and background, with fewer limits

#### **Operations on Processes**

- System must provide mechanisms for:
  - process creation
  - process termination

#### **Process Creation**

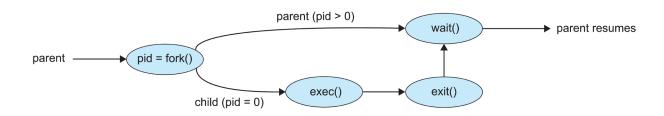

- Parent process creates children processes, which, in turn create other processes, forming a tree of processes
- Generally, process identified and managed via a process identifier (pid)
- Resource sharing options
  - Parent and children share all resources
  - Children share subset of parent's resources
  - Parent and child share no resources
- Execution options
  - Parent and children execute concurrently
  - Parent waits until children terminate

# **Process Creation (Cont.)**

- Address space
  - Child duplicate of parent
  - Child has a program loaded into it
- UNIX examples
  - fork() system call creates new process
  - exec() system call used after a fork() to replace the process' memory space with a new program
  - Parent process calls wait() for the child to terminate

#### **Process Termination**

- Process executes last statement and then asks the operating system to delete it using the exit() system call.
  - Returns status data from child to parent (via wait())
  - Process' resources are deallocated by operating system
- Some operating systems do not allow child to exists if its parent has terminated. If a process terminates, then all its children must also be terminated.
  - cascading termination. All children, grandchildren, etc. are terminated.
  - The termination is initiated by the operating system.

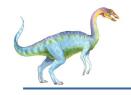

# **Interprocess Communication**

- Processes within a system may be independent or cooperating
- Cooperating process can affect or be affected by other processes, including sharing data
- Reasons for cooperating processes:
  - Information sharing
  - Computation speedup
  - Modularity
- □ Cooperating processes need interprocess communication (IPC)
- Two models of IPC
  - Shared memory
  - Message passing

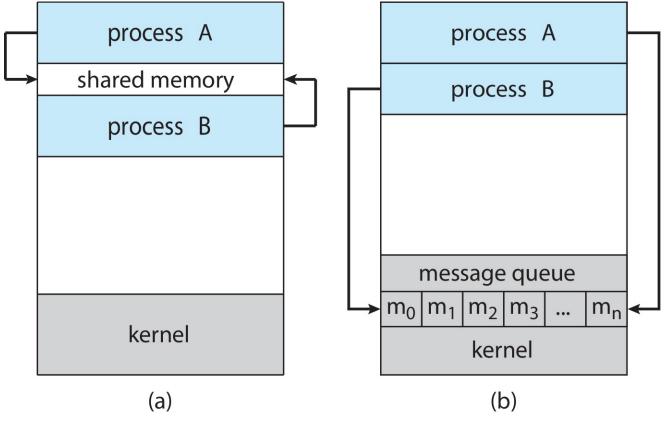

#### **Communications Models**

(a) Shared memory.

(b) Message passing.

#### **Interprocess Communication – Shared Memory**

- An area of memory shared among the processes that wish to communicate
- The communication is under the control of the users processes not the operating system.
- Major issues is to provide mechanism that will allow the user processes to synchronize their actions when they access shared memory.
- Synchronization is discussed in details in Chapters 6 & 7.

#### **Producer-Consumer Problem**

- Paradigm for cooperating processes, producer process produces information that is consumed by a consumer process
  - unbounded-buffer places no practical limit on the size of the buffer
  - bounded-buffer assumes that there is a fixed buffer size

# **Bounded-Buffer – Shared-Memory Solution**

#### Shared data

```
#define BUFFER_SIZE 10

typedef struct {
    . . .
} item;

item buffer[BUFFER_SIZE];
int in = 0;
int out = 0;
```

# **Producer Process – Shared Memory**

#### **Interprocess Communication – Message Passing**

- Mechanism for processes to communicate and to synchronize their actions
- Message system processes communicate with each other without resorting to shared variables
- IPC facility provides two operations:
  - send(message)
  - receive(message)
- ☐ The *message* size is either fixed or variable

#### **Message Passing (Cont.)**

- ☐ If processes *P* and *Q* wish to communicate, they need to:
  - Establish a communication link between them
  - Exchange messages via send/receive
- Implementation issues:
  - How are links established?
  - Can a link be associated with more than two processes?
  - How many links can there be between every pair of communicating processes?
  - What is the capacity of a link?
  - Is the size of a message that the link can accommodate fixed or variable?
  - Is a link unidirectional or bi-directional?

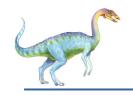

#### **Direct Communication**

- Processes must name each other explicitly:
  - send (P, message) send a message to process P
  - receive(Q, message) receive a message from process Q
- Properties of communication link
  - A link is associated with exactly one pair of communicating processes
  - Between each pair there exists exactly one link
  - The link may be unidirectional, but is usually bi-directional

#### **Indirect Communication**

- Messages are directed and received from mailboxes (also referred to as ports)
  - Each mailbox has a unique id
  - Processes can communicate only if they share a mailbox
- Properties of communication link
  - Link established only if processes share a common mailbox
  - A link may be associated with many processes
  - Each pair of processes may share several communication links

#### **Indirect Communication**

- Operations
  - create a new mailbox (port)
  - send and receive messages through mailbox
  - destroy a mailbox
- Primitives are defined as:

send(A, message) - send a message to mailbox A
receive(A, message) - receive a message from mailbox A

#### **Indirect Communication**

- Mailbox sharing
  - $P_1$ ,  $P_2$ , and  $P_3$  share mailbox A
  - $P_1$ , sends;  $P_2$  and  $P_3$  receive
  - Who gets the message?
- Solutions
  - Allow a link to be associated with at most two processes
  - Allow only one process at a time to execute a receive operation
  - Allow the system to select arbitrarily the receiver.
     Sender is notified who the receiver was.

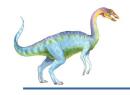

# **Synchronization**

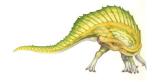

- Message passing may be either blocking or non-blocking
- □ Blocking is considered synchronous
  - Blocking send -- the sender is blocked until the message is received
  - Blocking receive -- the receiver is blocked until a message is available
- Non-blocking is considered asynchronous
  - Non-blocking send -- the sender sends the message and continue
  - Non-blocking receive -- the receiver receives:
    - A valid message, or
    - Null message
- Different combinations possible
  - If both send and receive are blocking, we have a rendezvous

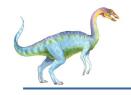

# **Producer – Shared Memory**

```
message next_produced;
while (true) {
    /* produce an item in next_produced */
    send(next_produced);
}
```

# **Consumer- Shared Memory**

```
message next_consumed;
while (true) {
    receive(next_consumed)

    /* consume the item in next_consumed */
}
```

# **Buffering**

- Queue of messages attached to the link.
- Implemented in one of three ways
  - Zero capacity no messages are queued on a link.
     Sender must wait for receiver (rendezvous)
  - 2. Bounded capacity finite length of *n* messages Sender must wait if link full
  - 3. Unbounded capacity infinite length Sender never waits

# **End of Chapter 3**
